Difference of age differences in disturbed census mean
(B_late−B_early)−(A_late−A_early), or (F_late−F_early)−(E_late−E_early); all 20 declared contrasts.
Each interval subtraction uses [l₁−u₀, u₁−l₀]; bounds retain unresolved detected sources.
Inputs: [Σ Q_D/5, Σ C_D/5] over five censuses; units: detected source observations per census.
An interval excluding zero supports a signed contrast within these operational envelopes, not independent-population uncertainty.
Each layout includes its removed-clone position; A/B and E/F are different spatial contrasts. Elapsed ages are not homologous phases.
Five census times per world, 160 deterministic worlds; recovery/population comparisons do not establish H1, H3, evolvability or RSI.
